1985

1985

2015

2015

Were the dire predictions of 1985 about AIDS correct?

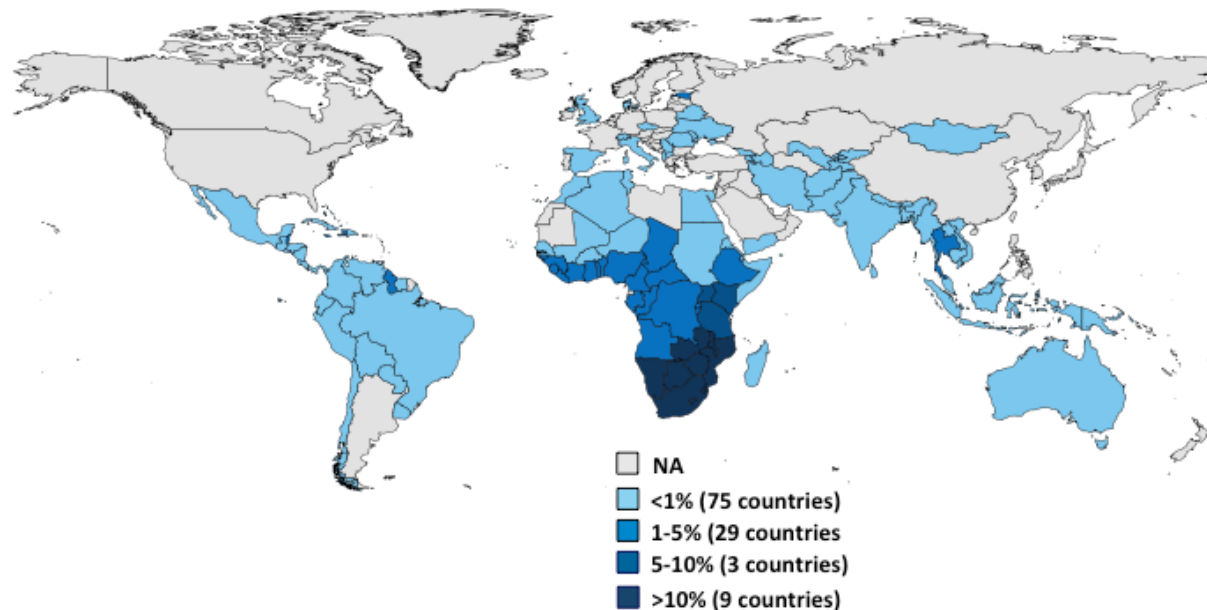

To a large extent: yes

- Worldwide 35 million people are currently living with HIV. Since the start of the epidemic, around 78 million people have become infected with HIV and 39 million have died of AIDS-related illnesses.
- In 2013, 2.1 million people became newly infected with HIV and 1.5 million died from AIDS.

But large geographical disparities

Adult HIV Prevalence Rate, 2013

Global HIV/AIDS Prevalence Rate = 0.8%

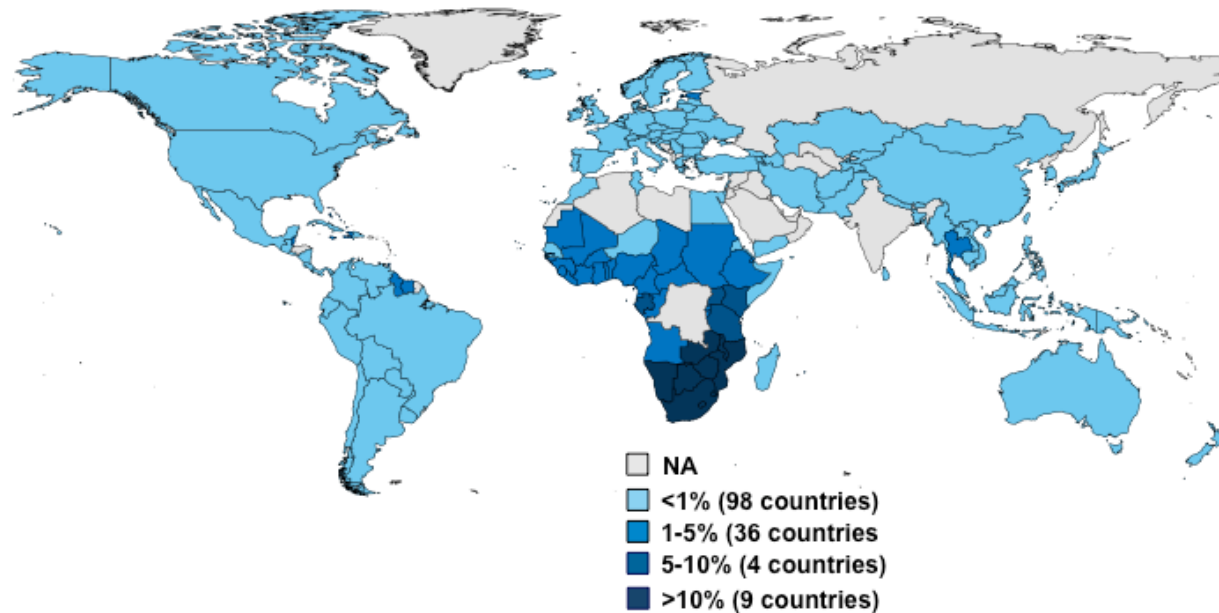

NOTES: Data are estimates. Prevalence rates include adults ages 15-49. The estimate for Sudan represents data for Sudan only. The estimate for South Sudan is 2.2%.

SOURCE: Kaiser Family Foundation, www.GlobalHealthFacts.org, based on UNAIDS, GAP Report; 2014.

Adult HIV Prevalence Rate, 2011

Global HIV Prevalence Rate = 0.8%

NOTES: Data are estimates. Prevalence rates include adults ages 15-49. The estimate for Sudan represents data for South Sudan. An estimate was provided for Sudan and is <1%.

SOURCE: Kaiser Family Foundation, www.GlobalHealthFacts.org, based on UNAIDS, Report on the Global AIDS Epidemic; 2012.

Antiretroviral therapy coverage for adults and children, 2013

The Moral and Fiscal Implications of Anti-Retroviral Therapies for HIV in Africa

Collier, Sterck and Manning, 2015

- Thanks to anti-retroviral therapies, people living with HIV in developing countries can now have a near-normal life at a cost of a few hundred dollars per year.
- Given this low cost of maintaining lives, there is a moral duty to rescue those who are infected.
- But treatment is life-long.
- Fiscal consequences of this duty create a financial quasi-liability which for some African countries is comparable to their debt-to-GDP ratios.

The Moral and Fiscal Implications of Anti-Retroviral Therapies for HIV in Africa (2)

Collier, Sterck and Manning, 2015

- Expenditures on prevention can pre-empt some of these liabilities.
- Extending the model to two players, they show that if the international community accepts part of the quasi-liability,(as it does), it should finance an equal share of prevention and treatment efforts.
- Any imbalance in this distribution would introduce moral hazard and lead to a sub-optimal level of prevention.

There ain't no cure for love!
And there is still no cure for AIDS...

For prevention, we need to
understand behavior

For prevention, we need to
understand behavior

HIV status in discordant couples in sub-Saharan Africa: a systematic review and meta-analysis

Oghenowede Eyawo, Damien de Walque, Nathan Ford, Gloria Gakij, Richard T Lester, Edward J Mills

Summary

Background Most couples affected by HIV/AIDS in sub-Saharan Africa live in discordant relationships. Men are thought to be the index case in most relationships, and most social marketing and awareness campaigns are focused on men. We investigated serodiscordance in stable relationships to establish the gender balance of index-case infections.

Men are Dogs. Aren't they?

On October 29, 2010, in Africa, behavior, global health, HIV/AIDS, prevention, research, by Karen Grepin

An interesting phenomenon in the HIV epidemic is that among African couples where at least one member is infected with HIV, in nearly two thirds of the cases only one member is actually infected – that is that there is a very high prevalence of “serodiscordance”. Serodiscordance can happen when transmission has not yet occurred between new couples or in a stable relationship when one partner acquires the virus elsewhere and introduces it into the relationship (for example if one member is cheating). Transmission of virus within existing couples is an important source of new infections and therefore prevention messages must still be targeted towards married or other stable couples. It is also part of the appeal of the “concurrency” hypothesis as a dominant mode of HIV transmission.

The stereotypical view of this situation is that African men are ones that introduce HIV into relationships – they are the ones that engage in extra-marital relationships, they are the ones that hire prostitutes, they are polygamous, they have more power in sexual relationships, etc – in short, they are dogs [exaggeration added]. A new study, which includes both a meta-analysis as well as secondary analysis using population based DHS data, suggests that this stereotype may not be justified – that women might be as likely to be the “index case” as men.

Oghenowede Eyawo and co-authors find:

The proportion of HIV-positive women in stable heterosexual serodiscordant relationships was 47% (95% CI 43–52), which shows that women are as likely as men to be the index partner in a discordant couple. DHS data (46%, 41–51) and our sensitivity analysis (47%, 43–52) showed similar findings.

Of course there might be biases that occur outside of relationship formation that might lead to more gender balance in more stable relationship vs. other forms of relationships that we might also care about. But the findings of this study are very interesting from a policy perspective because much HIV programming focuses more on men as index case than women and if this is not true than additional efforts must also be directed at women as well.

Surprising statistics (1)

At least 2/3 of the infected couples are **discordant** couples.

- This means that there is scope for prevention among couples.
- Could be due to the fact that couples are good at protecting themselves once one is infected.
- But unlikely, given that at least 71.5% (C) of couples where none has been for voluntary testing and that at least 88.9% (BF) agree that they did not use a condom at their last sexual intercourse

Surprising statistics (2)

Between 30.2% and 40.6% of infected couples are “discordant female”, where the woman is infected and not the man.

- At odds with common perception that unfaithful males are the “bridging” population between high-risk groups and the general population
- Apparently difficult to reconcile with self-reported levels of extra-marital sexual activity among married women.

Potential explanations for sizeable fraction of “discordant females”

- Extra-marital sex by married women is more common than reported.
- Extra-marital sex by married women is a very risky activity (male-to-female transmission rate higher, low condom use, extra-marital partner very likely to be infected).
- HIV infection of woman dates from before marriage or from previous marriage.

Women who have been in only one marriage and for at least 10 years

Results confirmed in subsequent meta-analysis

(Eyawo, de Walque, et al. 2010)

The proportion of HIV-positive women in stable heterosexual serodiscordant relationships was 47% (95% CI 43–52), which shows that women are as likely as men to be the index partner in a discordant couple. DHS data (46%, 41–51) and our sensitivity analysis (47%, 43–52) showed similar findings.

Conclusions on “Discordant female”

- Difficult to explain without sexual intercourse outside the union among women
- Need to keep in mind that not all extra-marital sex is consensual (rape, sexual harassment).
- It might be because extra-marital sex is more common than reported, or because, even if infrequent, women are very vulnerable to infection during extra-marital sex (ex: less likely to use condoms than single women and than married men)
- In any event, this seems to be an important source of vulnerability that needs to be targeted in prevention efforts.

Other conclusion: women have more agency in sexual relationships than sometimes thought in Geneva (or Washington)

How can we influence behaviors?

- Mass information, education, and communication (IEC) campaigns: are important, but might be complemented by strengthening motivation to act on that information.
- Research finds HIV testing and counseling, condom distribution can be cost-effective... but by themselves may not change trajectory of the epidemic.
- In Tanzanian youth:
 - Awareness of HIV prevention methods is high, but use of those methods is low.
 - Condoms are cheap, but low use

How can we influence behaviors?

- Novel approaches needed! Conditional cash transfers (CCT) have been promising in other domains ...
- Could they be used/adapted to help slow the AIDS epidemic?

World Bank rewards safe sex to boost fight against Aids in Africa

Funds of \$1.8m to back trial in Tanzania
By Andrew Jack in London

steps in the fight to tackle Aids, which claims 2m lives a year. In spite of billions of dollars spent annually on treatment and prevention worldwide, there were about 2.5m new HIV infections in 2007, predominantly in Africa. Carol Medlin from the University of California, San Francisco, one of the researchers, said "We hope this 'reverse prostitution' will make people think hard about the long-term consequences of their short-term

Cash for safe sex

Bribing Africans to be careful is bizarre - and worth a try

The phrase "new and daring" is not often paired with the words "healthcare intervention" but this idea goes beyond eye-patching young Tanzanians are to be bribed to stay HIV negative. A consortium that includes the William and Flora Hewlett Foundation and the World Bank is funding the experiment. Several thousand 15 to 20-year-olds in rural Tanzania will be given advice on sexual health, regularly tested for infections and paid almost \$20 a year if the tests are negative. The scheme will cause controversy. Are the funders saying young Tanzanians cannot be trusted to do what is good for them without a bribe? Yet the cash may increase the bargaining power of young women and give them an alternative to accepting money from older boyfriends. Cash today may be a more powerful incentive than the risk of an appalling disease many years hence. In the face of an appalling Aids epidemic, we should overcome our unease.

The question should be: can this plan really work? If it might, such "conditional cash transfer" programmes have become popular since the success of Mexico's Progresa programme, which paid parents if their children attended school and went to the health clinic. The approach has even been imitated in New York. Importantly, the scheme is to be evaluated in a controlled trial. That is welcome. Too few development policy ideas are given much as a new drug would be tested. That is welcome. Too few have learnt something valuable through scrutiny. The pilot would need millions of dollars to be successful. The world of development is more daringly evaluated than it should be. It should be rigorously evaluated and reported anyway.

Tanzanian experiment is a first step in efforts to test public health ideas more rigorously. Some participants placed in control arm not offered payment in order to track the effects of the programme precisely. "Conditional cash transfers" have already been used in Latin America to motivate poor parents to attend health clinics, and have their children vaccinated and schooled. Michael Bloomberg, the mayor of New York, last year unveiled a project to boost school attendance. The designers of the Tanzanian programme believe that payments of \$40 when combined with careful counselling could play an important role in reducing HIV infection, especially for vulnerable young women. The study will be conducted by the Ifakara Health Research and Development Centre in Tanzania, in conjunction with researchers from the University of California, Berkeley, the University of California, San Francisco and the World Bank. The Tanzanian trial programme, which is still subject to fine-tuning and ethical approval, will not specifically test for HIV, which is costly and already widely conducted in the country. It will use proxies including gonorrhoea, and guarantees any participant found to be infected receives state treatment.

Mobile clinic tested for syphilis and Trichomonas every four months over 2 years + HIV at baseline and months 16, 20 and 24

If in lottery intervention groups (T1 and T5) and STI negative, name entered in lottery boxes.

Size of the incentives

- The lottery rewards (US\$50 or US\$100) were perceived as significant amounts among respondents.
- From the Labor Force Survey (2008), the monthly salary for an agriculture worker is approximately 300 Maloti (about US\$30).
- Last month income as reported in the baseline survey was 276 Maloti (approximately US\$28) for males and 79 Maloti (approximately US\$8) for females.
- The average expected values of the lotteries were approximately US\$6.6 and US\$3.3, respectively.

Winners announced and received lottery prizes at public village level ceremonies

After 2 years, HIV incidence is 22% lower in the 2 lotteries groups, effect strongest for women

Prevalence of curable STIs decreased and safe sexual behavior increased.

For high-risk individuals, number of risky sexual encounters reduced by as much as
62 percent.

A woman in a white lab coat is handing a stack of money to a woman in a patterned dress. They are outdoors, with a crowd of people in the background. The scene is set in a rural area with stone buildings and trees.

HIV incidence can be reduced using financial incentives for remaining STI free

A lottery design is easier and cheaper to scale-up

Risk takers love lotteries

Future work: Swaziland

- Evaluate a combination of conditional cash transfers for education and lottery incentives for HIV prevention for young women aged 14-22.
- Test “scaled-up” version of the lottery: no STI test for everybody, but only for the lottery winners, who will win their prize if they are STI negative.

Postscript on responding to Ebola

- Snapshot of state of the Ebola epidemic
- Look at similarities and differences between the epidemics and their implications
- Can we learn from the HIV/AIDS response to inform Ebola response?

Number of cases and deaths as of 2/15/15

World Health
Organization

EBOLA SITUATION REPORT

18 FEBRUARY 2015

CASES/
DEATHS

(data up to 15
February
2015)

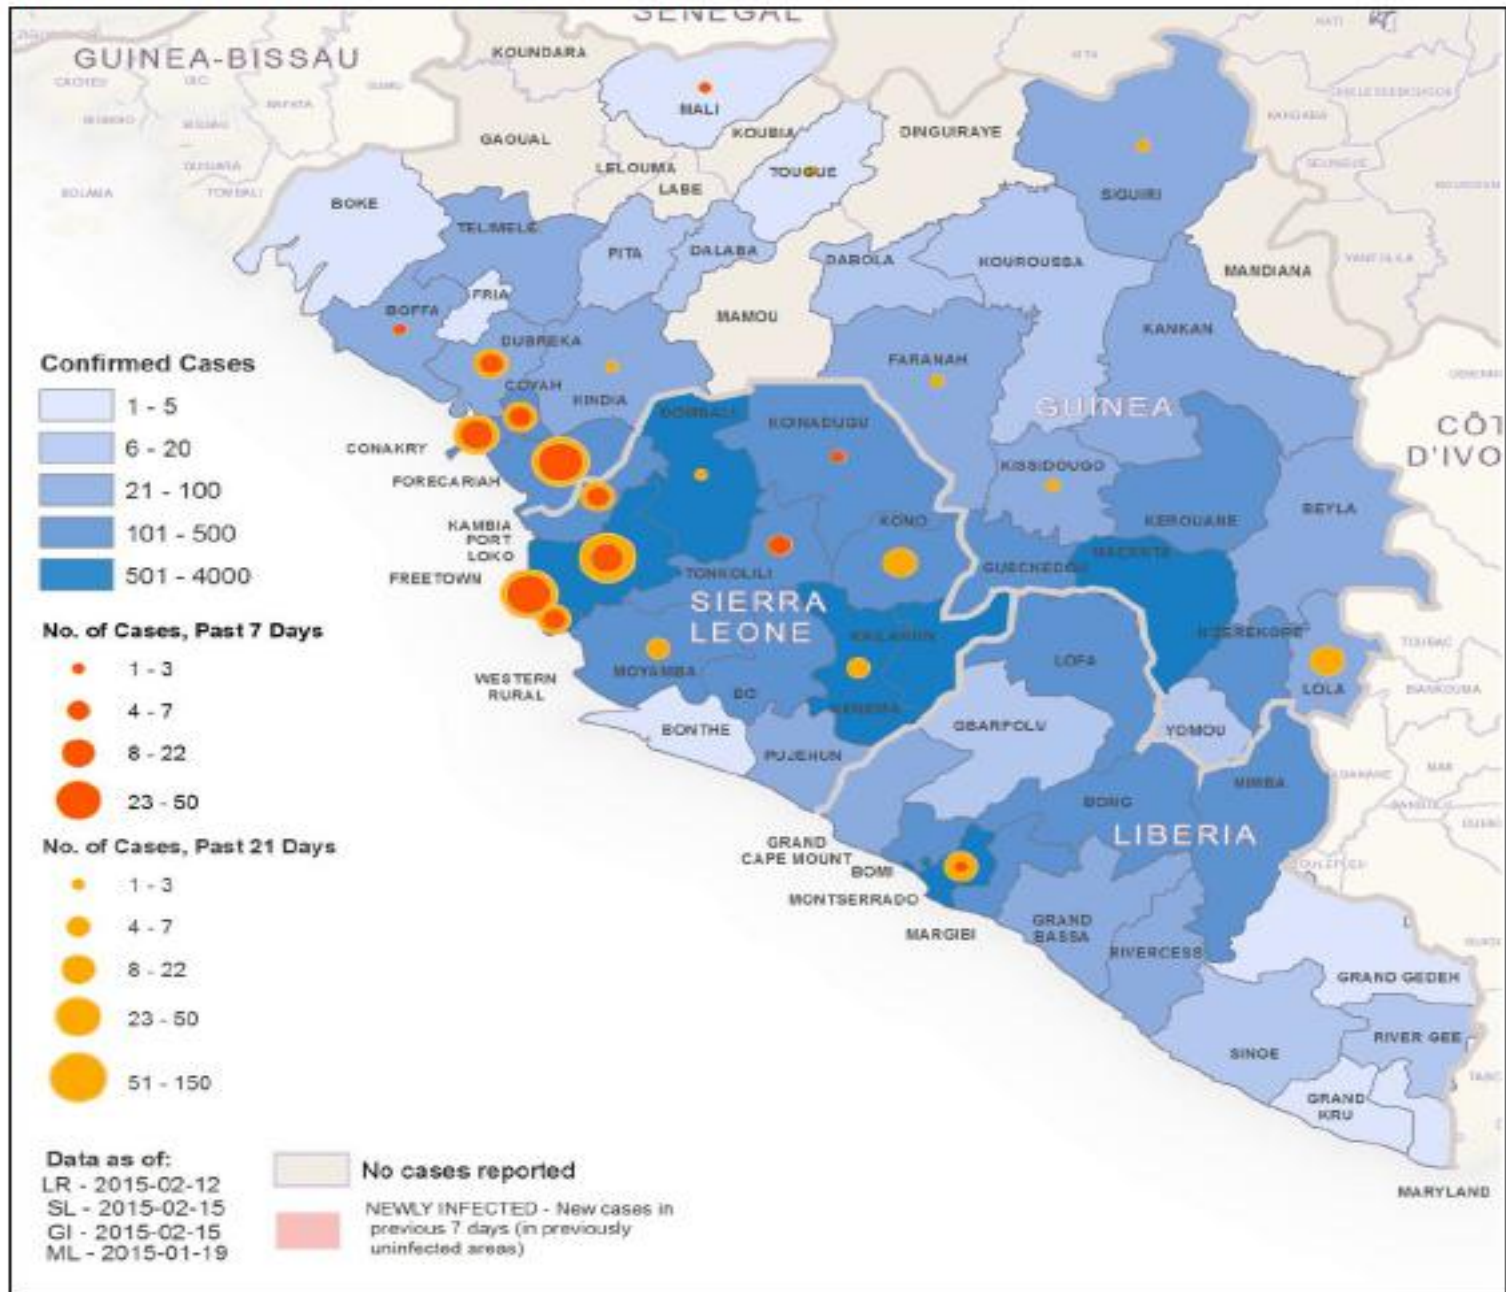

Figure 4: Geographical distribution of new and total confirmed cases

HIV/AIDS and Ebola

Comparing some facts

HIV/AIDS

- Infectious/Communicable disease
- Currently, no vaccine
- Transmission: unsafe sex, unsafe blood, in utero
- Prevention can target specific channels/behaviors: sex, blood (needle sharing, blood transfusion), prevention of mother to child transmission

Ebola

- Infectious/Communicable disease
- Currently, no vaccine
- Transmission: direct contact with blood, secretions, other bodily fluids or organs of infected people and with surface or materials contaminated by those fluids.
- Prevention needs to target a broader set of channels: health care, family based care, traditional burial practices (embalming), etc...

HIV/AIDS and Ebola

Comparing some facts (2)

HIV/AIDS

- Infectious even if no symptoms
- Time between infection and illness (AIDS) is 8-10 years in the absence of antiretroviral treatment.
- Initially very high mortality, but reduced with anti-retroviral
- No cure, but people under anti-retrovirals are less infectious

Ebola

- Not infectious until develop symptoms
- Time between infection and illness (incubation) is 2-21 days
- After that, patient either dead or recovered and immune (People who recover from Ebola develop antibodies that last for at least 10 years)
- Very high mortality (average death rate 40%)

Implications of differences

- Pool of (asymptomatic) infectious people much larger for HIV/AIDS
- Normally, HIV/AIDS more difficult to contain than Ebola
- But recent outbreak in West Africa more difficult to contain than earlier. First outbreak affecting large cities.
- And very fast and high mortality of Ebola creates fear, panic : “aversion” behavior
- Prevention for Ebola must target a broader set of behaviors: isolation and contact tracing play a more important role

Ebola is a major threat in Guinea, Liberia and Sierra Leone, but, at this stage, not elsewhere

	Guinea, Liberia, Sierra Leone	Rest of the world
Ebola new cases (last 12 months)	23,218	35
Ebola deaths (last 12 months)	9,365	15
HIV new cases (2012)	13,300	2,100,000
AIDS deaths (2012)	10,100	1,500,000
Deaths due to malaria yearly	-	627,000
Deaths due to diarrhea yearly	-	801,175

**More Americans
have been

DEATHS PER YEAR

Fear creates aversion behavior (Mead Over)

- Schools closure in Guinea, Liberia, Sierra Leone
- Rwandan immigrants refused access to school in New Jersey!
- Soccer Africa Cup of Nations moved from Morocco to Equatorial Guinea
- Travel restrictions, quarantines
- (To some extent similar issues at the beginning of HIV/AIDS. Restrictions on US visas for HIV positive individuals until 2008).

Fear creates aversion behavior and exacerbates economic cost

Figure 7: Sierra Leone - Visitor arrivals

Source: Sierra Leone Immigration Department.

In some villages, health workers have been attacked

- Health workers leaving their posts because they are the first exposed and not protected: mortality among health workers very high (Liberia 300 cases, 179 deaths among health staff).

To confront fear, build trust

Building trust

- Honest communication by government
- Work with community to explain isolation of patients, tracing of contacts
- US establishing treatment centers for affected health workers
- It is only after working with religious leaders that progress has been made to stop unsafe burial practices: develop “safe and dignified” burials.
- Same approach was gradually developed for HIV/AIDS (but not easy, still a lot of stigma).

In the long term, build more resilient health systems

- Continue surveillance for early detection of new cases – population need to trust the health system
- Improve motivation of health workers (for example through results-based financing).
- HIV/AIDS similar story: initially an increased burden on fragile health system. But now, in retrospect, in most contexts, the HIV/AIDS response contributed to strengthening health systems.

Thank you !

 - Alcohol abuse
 - Unhealthy food and lack of exercise
 - Risky sex

Disclaimer

Not my
autobiography!

Determinants of behavior: Example: education

Figure 2: HIV prevalence by education category, MRC General Population Cohort, Rural Uganda, 1990-2001. Individuals aged 18-29

An aside: compare with education and smoking in the US

Prevalence of smoking by education category in the United States, adults aged 25 and above: 1940-2000
Source: de Walque, JHR, 2010.
