Module 4: Progressivity Analysis

This presentation was prepared by Adam Wagstaff and Caryn Bredenkamp

Progressivity in ADePT in a nutshell

- Progressivity analysis asks whether across all sources of finance (taxes, social insurance, out-of-pocket spending, etc.) – it's the poor or better off who pay a higher share of their income on health care
- It calls for HH data on health spending by different sources, and NHA data on the shares of total health spending being financed through these same sources
- ADePT shows the budget share by source for each income quintile, and reports a summary progressivity index showing the progressivity of each source and all sources combined

The basic idea

The basic idea

- Equity in health care financing is a question about who pays (most) for health care
 - Note we're interested in payments via <u>all</u> sources, not just through out-of-pocket spending
- A health financing system is equitable if households make payments according to their ability-to-pay (ATP)
- Progressivity analysis compares low- and high-ATP households in terms of the share of their income (or consumption) that they pay towards health care
 - A progressive health financing system is one where high-ATP households pay a higher share of their income than low-ATP households

Why countries' financing systems may differ in their progressivity

- Different <u>sources</u> will likely vary in their progressivity:
 - Some may be progressive, others regressive, and still others proportional
 - Some sources may be more progressive than others
- Countries vary in their <u>financing mixes</u>—e.g. some rely more heavily on out-of-pocket spending than others
- Specific sources vary in their progressivity across countries—e.g. some countries have progressive tax systems, others don't

Financing mixes in 30 countries

Groupings of countries by dominant source of health finance

SHI as % total

Let's get measuring!

Data for progressivity analysis

These data come from household survey

Thailand – financing mix

| Quintile | # HH | Income | Тахеѕ | SHI contributions | Private insurance | Out-of-pocket spending |

| | | | | | | |
| | 7500 | 8000 | 1600 | 1250 | 10 | 50 |

These data come from the NHA

Two charts that <u>both</u> illustrate progressive health care payments

The left-hand chart implies the right-hand chart, and vice versa

The link between progressivity and inequality

- The Lorenz curve shows how unequally distributed income is
- Concentration curve shows how unequally distributed health care payments are <u>across the</u> income distribution
- Progressive payments are more unequally distributed (by income) than income

ADePT

Kakwani's progressivity index

- We measure progressivity as twice the area between the two curves
- This is Kakwani's progressivity index
- By convention it's positive for progressive payments, and negative for regressive ones

The link between Kakwani and the Gini

 The Kakwani index is also equal to the concentration index for payments minus the Gini coefficient for income, i.e. K = C - G

When payments are regressive

- Under regressive payments, the Lorenz curve lies <u>below</u> the concentration curve
- The Gini coefficient in this case is then <u>larger</u> than the concentration index
- So the Kakwani index K (= C – G) is <u>negative</u> for regressive payments

Assessing progressivity in total payments

- We want progressivity for each source, <u>and</u> progressivity for health financing <u>in total</u>
- The latter is easily calculated as a weighted average of the Kakwani indices of the individual sources, where the weights are the shares of total revenues coming from each source

 $K = (R_1/R)K_1 + (R_2/R)K_2 + ... + (R_N/R)K_N$

Here R₁ is the revenue raised from source #1, R is total spending, K₁ is the Kakwani index for source #1

How to do it in ADePT?

Z

What ADePT does

- ADePT produces the average amounts households spend on health by source for each quintile, the shares of income (or consumption) spent on health by source, and the shares each quintile accounts of total revenue
- ADePT also outputs the Kakwani index of progressivity, for each source and for total health finance
- Finally, ADePT produces charts showing for each quintile the shares of income spent on health by source, and the Kakwani progressivity chart with the Lorenz and concentration curves

What ADePT asks for

- For the household data, ADePT asks the user to indicate:
 - The income or consumption variable, and the health payment variables—out-of-pocket payments, private insurance, social health insurance contributions, and taxes
 - You'll need household size if you haven't already expressed everything on a per capita basis
- It's best to give ADePT the health financing mix from the NHA
 - It will use these shares to compute the progressivity of total revenues; otherwise ADePT will assume that <u>all</u> taxes go to finance health care!

Egypt (1997) as an example

- Revenues raised from taxes (direct taxes, indirect taxes, an earmarked cigarette tax), social health insurance, private insurance, and out-of-pocket spending
- NHA data from 1994-95 give the financing mix
- Household data from the 1997 Egypt Integrated Household Survey, which contains data on direct taxes, private insurance, and out-of-pocket payments. Ravi Rannan-Eliya imputed sales and cigarette tax payments, and social health insurance contributions
- N.B. The household totals in the dataset have already been adjusted for household size

Before opening ADePT

Go to the NHA and obtain the financing mix

Egypt example

| Subsector | % of revenues |
|---------------------------------------|---------------|
| Direct taxes | 4.69 |
| Indirect taxes | 28.29 |
| Earmarked cigarette tax | 3.00 |
| Social health insurance contributions | 6.67 |
| Private insurance | 5.57 |
| Out-of-pocket payments | 51.77 |

Indicate how Egypt compares with other countries

Show how the financial burden of health finance varies with income

Show the progressivity of different sources

Egypt's financing system is quite progressive by international standards

Countries are as follows. PI: Switzerland, USA; OOP: Bangladesh, China, India (Punjab), Indonesia, Kyrgyz Rep., Nepal, Philippines, Sri Lanka; SHI: France, Germany, Italy, Japan, Korea, Mexico, Netherlands, Taiwan, Brazil; Tax: Denmark, Finland, Hong Kong, Ireland, Malaysia, Portugal, Spain, Sweden, Thailand, UK.

Policy levers-i

- The progressivity analysis points to 2 types of policy lever:
 - 1. Make a financing source more progressive, or less regressive
 - Health ministries have limited scope to affect the progressivity of taxation. But they <u>can</u> raise or eliminate ceilings on SHI contributions, exempt the poor from copayments, etc.
 - 2. Shift the financing mix toward progressive sources, and away from regressive sources
 - Health ministries can raise the share of revenues financed publicly, reduce the out-of-pocket payments share, etc.
- ADePT results give a sense of how progressivity might change following different interventionsDePT

Policy levers-ii

- Examples of reforms that make a financing source more progressive, or less regressive:
 - Multiple examples of programs exempting the poor from copayments making out-of-pocket payments less regressive
- Examples of a reform that shifts the financing mix toward progressive sources, and away from regressive sources:
 - Mexico's Seguro Popular and Vietnam's Health Care for the Poor program both reduced out-of-pocket payments and introduced means-tested contributions supplemented by general revenues

Where to go from here?

Data sources for progressivity analysis

- For household data:
 - Household expenditure or budget surveys that capture:
 - Out-of-pocket payments
 - Private insurance payments
 - Social health insurance contributions—may need estimating
 - Direct and indirect tax payments—may need estimating
- For health financing mix:
 - NHA containing revenues raised from different sources (WHO NHA's contain this information)

Some cautionary notes

- Out-of-pocket payments
 - Make sure when you aggregate across different types of service, you're expressing everything in a common time-unit, e.g. annualize everything
 - Out-of-pocket payments should be net of any insurance reimbursement
- Taxes
 - Taxes account for quite a large share of health finance in most countries. Yet household expenditure datasets often have little if any information on taxes paid
 - Other people may already have imputed taxes for your survey. Get their data!
 - Otherwise you'll have to impute them yourself using tax rules. It's a huge job, and a heroic one because of evasion and avoidance, and because of lots of missing information. Seek specialist help!
 - In imputing taxes, incidence assumptions are needed

Topics in the 2nd equity-in-health-finance module

- Progressivity is one aspect of equity in health finance. It relates to the idea of vertical equity—the idea that households with greater ability-to-pay should pay more
- There's another aspect of equity—horizontal equity. Two households with the same ability-to-pay may end up (unfairly) spending different amounts on health care
 - For example, households in one social insurance scheme may pay less than people in another scheme even if they have the same income, because their contribution rates differ
 - One scheme may have a more risky membership profile, so that the household with the higher contribution rate has to crosssubsidize the elderly while the household with the lower contribution rate doesn't
- ADePT measures horizontal equity, via a decomposition of the redistributive effect of health financing
